

Proclamation 2024: Publisher-Identified Error Corrections Addendum

This report lists errors identified by publishers and includes the proposed corrections. This is an addendum to the Proclamation 2024: Publisher-Identified Error Corrections report presented to the State Board of Education at the September 2023 meeting and only contains additional changes reported by publishers after that meeting through November 7, 2023. These corrections must be made as a condition of adoption by the State Board of Education.

<i>McGraw Hill Texas Physics Student Edition</i>	9780077006846		854	Paragraph 2		Only about the innermost 10 percent of a star's mass can undergo nuclear reactions, because temperatures outside of this core never become hot enough for reactions to occur. Thus, when the hydrogen in its core is gone, a star has a helium center and outer layers made of hydrogen-dominated gas. Some hydrogen continues to react in a thin layer at the outer edge of the helium core, as illustrated in Figure 22. Meanwhile, as the core contracts, the temperature in the core becomes hot enough, at 100 million K, for helium to react and fuse into carbon. The increased energy output from helium-to-carbon fusion in the core increases the rate of hydrogen-to-helium fusion in the outer layer of the core. This in turn forces the outer layers of the star to expand and cool. The star is considered a giant because it is larger, but the color is red because the outer surface is relatively cool. Red giants are located to the upper right of the main sequence on the H-R diagram.	Only about the innermost 10 percent of a star's mass can undergo nuclear reactions because temperatures outside of this core never become hot enough for reactions to occur. When the hydrogen in its core is gone, a star is left with a helium center and outer layers made of mostly hydrogen gas. The helium core then contracts and heats up, allowing a thin shell of hydrogen to fuse around it, as illustrated in Figure 22. The ignition of the hydrogen shell causes the outer hydrogen layers to expand and cool. The star is considered a giant because it is larger, but the color is red because the outer surface is relatively cool. As helium builds up, the temperature in the core becomes hot enough, at 300 million K, for helium to react and fuse into carbon. The fusing helium causes the outer hydrogen layers to expand and cool even more. Red giants are located to the upper right of the main sequence on the H-R diagram.

<i>McGraw Hill Texas Physics Student Edition</i>	9780077006846		392	Paragraph 3		Tectonic plates move apart along divergent boundaries. Most divergent boundaries are found along the seafloor. As shown in Figure 13, magma rises along the boundary as plates separate. The magma hardens and forms a mid-ocean ridge. A mid-ocean ridge is a continuous mountain chain on the ocean floor. Volcanoes and earthquakes are common along the ridge. Some divergent boundaries form on continents. When continental crust separates, the stretched crust forms a long, narrow depression called a rift valley. A rift system has worked to separate the African and Arabian plates over the course of 30 million years.	Tectonic plates move apart along divergent boundaries. Most divergent boundaries are found along the seafloor. As shown in Figure 13, magma rises along the boundary as the plates separate. Once it reaches the surface, the magma hardens and forms a mid-ocean ridge. A mid-ocean ridge is a continuous mountain chain on the ocean floor. When continental crust separates, the stretched crust forms a long, narrow depression called a rift valley. A rift system has separated the African and Arabian plates over the course of 30 million years. Most divergent boundaries have volcanoes and earthquake activity.

Southwestern California and Baja will become an island off the coast of Oregon in 20 million years.	Ask students what will eventually happen to southwestern California and Baja California if present plate motions continue for millions of years at a rate of about 5 cm/y. Southwestern California and Baja California will become an island off the coast of Oregon in 20 million years.
McGraw Hill Texas Physics Teacher Edition	9781265775384		833	"Page 541 Figure 9 Look Closer," answer		The boy could not see his full height because light rays from the lower half of his body would be at such a large angle of incidence that the reflected ray would not reach his eye. However, because of the law of reflection, the boy could see most of his height by moving away from the mirror.	If the top of the mirror is aligned with the boy's eyes, then light rays from his feet will be directed to his eyes; however, he won't be able to see the part of his head that is above his eyes. If the mirror is moved upward so that the top is aligned with the top of his head, he can see his head, but his feet will be cut off. So while light from his entire height is reflected by the half mirror, his eyes are not always positioned to see his full height as a virtual image.
